MuTaTeD! - Music Tagging Type Definition

A project to provide a meta-standard for music mark-up by integrating two existing music standards

(Report Jan 2000)

Dr. Stephen Arnold
Carola Boehm
Dr. Cordelia Hall

University of Glasgow
Department of Music

CONTENTS:

I. Introduction

(by Dr. Stephen Arnold)

"Music" is a term which has to stand for a variety of things. One reads music; one plays music; one listens to music; one studies music; one even "makes" music.

At the end of everything, Music has to have a sonic existence: that is the whole point of it. But to support the sonic manifestation, we have developed ancillary representations which have a number of functions.

The one with a long history is notation. In its earliest forms, when cultural transmission was essentially aural, it captured the barest minimum of information. In no way was it meant to specify every detail of performance, since that kind of information was conveyed via the aural-traditional route which depended on experts so familiar with their musical culture that there was no necessity for the notated to forms even to attempt to do so.

For much of our recorded music history, notated forms of music have not been created as authoritative statements aimed at the archives of posterity. They have been practical documents created to support performance, and they tend not to include details of *how* to perform a work (e.g. details of dynamics, articulation, even instrumentation and tempi variation) but a rather more conceptual representation of the composition in abstract. This is especially understandable when one bears in mind that composers were usually also performers who frequently led performances of their own music, and that there was therefore a shared, unwritten, aural traditional framework which prescribed conventions of performance.

As Music became less localized, more massive in its forces and time-scales, and more individualized and differentiated in style and content, the need for more more highly specified scores and parts became ever more acute, until almost every conceivable nuance of performance was explicitly characterized by graphical or textual signing within the notated version. Think of Mahler's Symphonies. This tendency has continued, although, to this day, there are observable, inevitable (and desirable) deviations between notated and performed manfestations of the work.

With the move to highly specified musical notation has come a scholarly approach to music which accords a privileged place to the notated representations of the work. Within our musical culture, what is meant by the term "music" is, as often as not, the score rather than the performance. Scholars study notated works for many kinds of evidential data relating to the work's history or content, while performers confidently develop their performnces guided only by the notated form of the work.

With the burgeoning of the Information Age, new dimensions for Music are opening up. At the conceptual level, we now conceive of an information space of many inter-related and interleaved dimensions, capable of fulfilling a wide variety of musical functions and needs, not only within purely musical contexts, but also as part of broader multimedia frameworks. The gap between concept and realization is, however, still frustratingly wide. Standards for text, image, networks, metadata, etc., are fields of intense research and commercially oriented activity, raising the prospect of exploting critical masses of content-rich, time-based media over wide-area networks within the framework of , for example, MPEG4, MPEG7, SDIF and SMIL. But the situation regarding standards for musical data is confused, the

confusion arising from the complexity and endless variety of musical data, much of which is "culture specific" rather than genuinely generalizable.

Even though there are as yet no universal, platform-independent, generic, established standards for music representation, music information or tagging, significant steps are now being taken to provide structures for music data and tools for display, searching and manipulation which will undoubtedly prove to be of great value, not only in the rarified realms of academe, but also throughout the "real" commercial worlds of the music and media industries.

The JISC-funded *MuTaTeD!* project is one of several within the fields of music technology, music information and computer music, which are running in the Department of Music at the University of Glasgow. Ours is a step-by-step approach. *MuTaTeD!* attempts to validate through implementation the concept of integrating two existing music-representation standards, namely SMDL (Standard Music Descrpition Language) and NIFF (Notation Interchange File Format). This integration was forseen and advocated in the NIFF specification of 1995.

An application based on this integration should support (i) via SMDL, the representation of Music as a time-structured entity, and (ii) via NIFF, the high-quality display of the notated version. An important outcome of *MuTaTeD!* is the first and only (or so we believe!) SMDL-to-NIFF converter, which allows NIFF-compliant notation editors such as LIME, CPN, IGOR and SmartScore to display SMDL-encoded music data.

The Report which follows is divided into two principal sections: (i*)* a discussion of the challenges of music representation and retrieval; (ii) a detailed introduction to and description of the parsers and compliers used to implement the *MuTaTeD!* prototype. A final section (iii) considers the outcomes of this project and looks forward to future developments in this research area. In particular, we outline *MuTaTeDII* which builds on *MuTaTeD!* by designing and implementing a music-information retrieval system with delivery/access services for encoded music.

We have taken steps to communicate our work to others working in the fields of music encoding, arts and humanities computing and content-based retrieval: some of the more important conferences and meetings are listed below. We have also targetted specialist email ansd news groups, organized and taken part in specialized workshops and been invited to present at others. We shall be co-organizing an important international workshop as part of the International Computer Music Conference in Berlin in August 2000.

We therefore believe that we have attained the goals of the original MuTaTeD! proposal, both in terms of the its technical objectives and of its dissemination objectives.

While we are confident that what has been accomplished within MuTaTeD! is of considerable importance, we recognize that, within the broadest context of music-information representation and retrieval, the steps we have taken, difficult though they have been, are fairly modest in their scope and that considerable further work remains to be done. For this reason, we have embarked on a second phase of MuTaTeD! (MuTaTeD2!), which aims to embed MuTaTeD! outputs in a considerably broader functional context.

II. Achievements and Deliverables

(by the MuTaTeD! Team)

Despite the work being limited to the equivalent of a 4-month FTE project, a significant amount of territory has nevertheless been covered. Principal achievements are:

- proof of concept for the integration of SMDL and NIFF (see Chapter III.8)
- development, revision and integration of a SMDL DTD and a NIFF DTD (see Chapter IV.6 and Appendices A and B)
- the first SMDL to NIFF converter, complementing the Mounce Niff→SMDL converter (Cantate) (ditto)
- expert and user workshops (see Chapter II.1)
- establishment of a small but continuing influence of the MPEG7 standardization process aimed at incorporating compatibility with SMDL. (see Chapter II.1 and Appendix C)
- involvment in the development of the revised SMDL standard, as this will be updated due to changes in HyTime.
- presentations, workshops and invitations to research meetings (Chapter II.1)

1. Conference Papers and Workshops

The results of this works were presented in several large conferences and meetings, national and international:

ARS ELECTRONICA FESTIVAL, Linz, AUSTRIA, September 5 - 8 1999
Meetings of CUIDAD and CIRCUS,
Invited Paper Presentation. Title: "Music Tagging Type Definition".

CIRCUS Meeting, Dublin, Ireland, October 20-22 1999
Invited Paper Presentation. Title: "Metadata and CIRCUS".

DRH99, London, UK, September 12-16 Sept 1999
Paper Presentation: "MuTaTeD!"

Expert and user workshops provided the means of early dissemination of the results:

DRH99, London, UK, September 12-16 Sept 1999
Co-organized Expert Workshop "Music Information Retrieval"

Workshop in Glasgow, 15 December 1999
Organized local workshop "Systems for Music Information Representation and Retrieval"

2. Contact with relevant research groups

Contact with local and external research groups, mailing lists and newsgroups made us aware of other developments in this topic-area and enabled us to become involved in the processes of standardization or creation for SMDL related applications.

Our local research group meets weekly. It is made up of the research assistants, music technology lecturers and academic related staff.

Projects run within the Music Department and relevant to MuTaTeD! are:

Direct software evaluation of Music Notation Packages for an Academic Context
(Project Management: Carola Boehm and Stephen Brandon)
Evaluating music notation packages in the context of a multi-user, multi-computer, networked academic music environment.
Funded by JISC and Universities & Colleges Information System Association (UCISA).
(http://www.pads.ahds.ac.uk/notation_eval.html).

A system for Music-Information Retrieval of Encoded Music (MuTaTeD'II)
(Project Management: Carola Boehm)
The aim of the proposed project is to design and implement a music-information retrieval system with delivery/access services for encoded music. It builds on the output on the MuTaTeD! project. The prototype service will provide a user-friendly, web-based search/browse/query interface to access musical content. Funded by the Library Information Commission and started in 1999.

External Working groups include:

Audio MPEG7 AdHoc group (International scope)
Involvement within the framework of the MPEG7 working group (MPEG ISO/IEC JTC1/SC29 WG11) (http://www.darmstadt.gmd.de/mobile/MPEG7/) to ensure the integration of technologies for information retrieval vital for communities of music libraries and digital music-libraries.

EU-funded working group CIRCUS (European Scope)
Content Integrated Research into Creative User Systems (http://www.circusweb.org), CIRCUS is a working group funded by the EC's Esprit programme. CIRCUS brings together artists, designers, performers, theorists and computer scientists to debate the research issues posed by the next generation of advanced information technology for the creative and performing arts, media and the electronic publishing industry (in its broadest sense). It brings together partner institutions in the UK, Ireland, Finland, France, Germany, Netherlands and Spain. CIRCUS advises the EC on the integration of content and technology in terms of creative pull vs technology push.Glasgow contributes to the subgroup dealing with metadata standards for the creative arts user community.

MusicWeb Connect (European Scope)
Within the european-funded MusicWeb Connect project Glasgow has the reponsibility of technical co-ordination, evaluation and dissemination. It aims to integrate and implement music-specific on-line interactivity and collaborative working tools. Two technologies underpin this project, a) the GUIDO Music Representation Language and Note Server for dynamic music representation and b) "Gentle", the educational application built upon the Hyperwave Information/Knowledge Management System. The collaborating institutions are the Royal Conservatory of Music and Dance Den Haag (Project Co-ordination), Netherlands; Institute for Information Processing, Graz, Austria; Technische Hochschule Darmstadt and Hochschule für Musik Hanover, Germany; and IRCAM, France. Funded by EU Connect Programme and German and Dutch national funding.

3. Additional Dissemination Activities

The success of the international expert workshop organized under the auspices of MuTaTeD! as part of DRH99 has led to a further workshop to be held in the University of Massachusetts to which we have been invited.
We are organizing a further workshop under the auspices of the Internationla Computer Music Conference 2000, where we are also presenting formal papers relating to MuTaTeD!.

SAMURAI (2nd Symposium on Adequate Music Representation Issues), Vancouver, CA
Invited paper. June 16-19 2000

WEDELMUSIC, Firenze, ITALY
Invited as Member of Expert User Group to the first meeting of the EU-funded working group WedelMusic. April 1-2 2000
The objectives of the project are:

- to make possible the distribution of interactive music via the internet managing IPR and integrating audio, symbolic and image formats within a unified model
- to adopt a model for distributing music, taking into account the user needs

Paper (acceptance to be confirmed): "Music Tagging Type Definitions, MuTaTeD I and II : Systems for Music Representation and Re-trieval", Special Session on Sound and Music Technology within the EUROMICRO WORKSHOP on Multimedia and Telecommunication, Maastricht, Netherlands 4-7 September 2000

III. Systems for Music Representation and Retrieval

(by Carola Boehm)

1. Abstract

The project MuTaTeD! validated the concept of integrating two existing music representation standards: SMDL (Standard Music Description Language) and NIFF (Notation Interchange File Format). An application with the combined implementation of these two standards, SMDL and NIFF, supports the representation of music as a time-structured entity in its own "gestalt" as it is conceived and yet provides a standard for high-quality display via the NIFF format. The paper will discuss the general issues surrounding music information representation and music information retrieval, present the result of the UK-JISC funded "proof-of-concept" project: MuTaTeD! (Music Tagging Type Definition) and inform about further development within the UK-Library Information Commission funded MuTaTeD'II project and its MPEG7 involvement.

2. The Broad Context

A serious problem for IT today concerns ***Information Overload***. When, as now, the internet is becoming the platform, the browsers become the operating system, and applications become services[1], services to access music content have to define new methods of storing and distributing time-based data if they are to serve large quantities of high-quality information across wide area networks (WANs). Future information services will need to carry the burden of extensive metadata management, - content searching and manipulation of time-based data - if they are to facilitate intelligent access and efficient delivery to their user communities.

It is now, therefore, quite widely accepted that there needs to be development in three areas (i) ***Information Structure*** (ii) ***Information Representation and*** (iii) ***Information Access.***
In a number of IT sectors, there has been considerable progress in user interfaces, metadata management systems for access, information retrieval, workflow management, and similar areas. But in the area of Music

- the most widely encountered music information structure is midi
- visual information representation over WANs is largely restricted to static images
- music information retrieval is still in its infancy.

While this leaves plenty of scope for researchers, there is a sense that users have still to benefit as fully within the area of Music as they clearly have in other domains.

3. The Music-Specific Context

Accessing and manipulating time-based data over wide-area networks is a research area ready to deliver its first results. For a variety of tasks, such as automatic page-turning and slide-shows, and within a variety of fields, such as multi-media applications and professional video or media companies, there is a requirement for a language that describes time-based media in its structure.

Two main options seem to be possible here:

- handle the media files as they are and synchronize their interaction with each other, or
- use a structured language to represent time-based media files, such as those associated with music, as a time-based medium within its own time-dependent structure.

[1] Kostas Glinos (EU, DG3), "Information Access and Interfaces", presentation for the last call of the 4th framework, 29 September 1997, Brussels.

The first option has yielded solutions that have already been commercially exploited, e.g. interaction of sound and movies, parallel depiction of scrolling text and movies, web slide-sound shows, etc. The second option has so far been neglected, so that the Music community is left without the musical equivalents of, for example, SGML (Standard Generalized Markup Language)[2] and XML (eXtensible Markup Language)[3] and packages to handle them.

"Music Representation Languages" are essentially a means to describe certain musical elements and their time-relation to each other. At the macro level, such a language might represent a sequence of four sound files played one after the other, corresponding to the four movements in a symphony. At the micro level, it might represent single notes on several staffs in their relative "time-positions". Thus, within this model of a "time-based media structure", by heightening the detail of granularity, we conjoin the two options outlined above.

An application with the combined implementation of two standards, SMDL (Standard Music Description Language)[4] and NIFF (Notation Interchange File Format)[5], would support the representation of music as a structured, time-based entity in its own gestalt, - while simultaneously supporting high-quality display via the NIFF format. The publication of the SMDL standard draft in 1995 was recognized in the NIFF specification of the same year when it proposed this very combination for applications.

Among applications which might be founded on this concept are:

- Platform independent file interchange (music software, web)
- Intelligent and dynamic access to structured music (libraries, education)
- Using music-recognition functionality, easy and instant access to a critical mass of music (sheet music sales and loans, music publishers, performers, music and audio distributors)
- Collaborative creation and working processes and the synchronization of time-based media entities of the same and different type (media production industry)

As mentioned above, in order to achieve this, the existence and acceptance of a language that describes time-based media in its time-based structure is required and with it the possibility to represent it in a musical way. The development and adoption of such a language as we envisage will make possible the realization of these objectives.

The basic idea of the MuTaTeD! Project (Music Tagging Type Definition) grew out of these considerations and suggested the following primary project goals:

- the proof of concept of integrating two existing standards, one for music content (SMDL) and one for music score representation (NIFF)
- the use of a standard Meta-DTD for music-tagging languages

[2] SGML, Standard Generalized Markup Language, ISO 8879:1986 of ISO/IEC JTC1/SC34, see http://www2.echo.lu/oii/en/docstand.html#SGML 28/02/00.

[3] XML, eXtensible Markup Language, W3C and IETF, see http://www2.echo.lu/oii/en/docstand.html#XML 28/02/00.

[4] SMDL (Standard Music Description Language) is a HyTime application that conforms to international Standard ISO/IEC 10744. See below.

[5] Notation Interchange File Format, created 1995 in collaboration with several music companies. See below.

4. Music Representation Standards – The Historical Context

Research into Music Representation Standards is not new. There have been many and varied approaches to standardised music representation. The following, historically oriented listing helps show the context for our current efforts.

Independently of (and in parallel with) "conventional" music notation, numerically based systems for encoding musical information have been devised, perhaps governed by an idealistic Pythagorean sense[6] that numerical abstraction and elegance was especially appropriate. But they were also to fulfil a practical need, at a time predating audio recording, to capture musical data as it was being played – a task for which common music notation is not at all well suited[7].

Using typewritten text and early computers, substantial archives of incipits and melodies were developed, giving rise to an ASCII-based notation. These holdings may still be found in many catalogues of music.[8]

With the development of professionally oriented music applications for the computer, new data structures, file formats, and music description standards emerged with almost with every application. The Music Notation software applications, in particular, were forced to create their own underlying music data structures to contain all the information needed to print music. In the absence of established and widely adopted standards, this was inevitable if the applications were to be of any practical use. Surprisingly, perhaps, there was not much impetus to agree a joint standard.

NIFF (Notation Interchange File Format)[9] was the first (and only) commercially-based effort by several companies to agree on an interchange file format for Notation. Although there are now a few NIFF-compliant programs, all the most widely used notation and music programs are still (early 2000) not capable of reading NIFF. Perceptions of their commercial interest appear to lie behind various music companies' failure to follow through with previously announced plans for NIFF implementation. This is difficult for the Music user community to bear, forced as it is to struggle on with MIDI, which cannot and indeed was never intended to support the full extent of the needs of the field.

Recent activity to revive NIFF-related development is largely to the credit of the user community rather than commercial concerns, The MuTaTeD! Project can reasonably be claimed as an important part of this recent push forward.

A positive development can be seen with music tagging languages. The number of text-based music languages, cognate with SGML/XML/SMDL, is rising. A number of groups are pushing for standardisation of a single language to be used over the web. There are developments spinning off from XML under the W3C[10], and developments with SMDL (Standard Music Description Language)[11], backed by MuTaTeD! and their work within MPEG7[12].

9 See "Notation Interchange File Format", http://www.musitek.com/niff.html 26/02/00 and Cindy Grande, "NIFF" in [Selfridge-Field 1997] p.491-511.
10 World Wide Web Consortium, http://www.w3.org/
11 ISO/IEC DIS 10743, Standard Music Description Language (SMDL) see http://www2.echo.lu/oii/en/audio.html#SMDL, 26/02/00 and Sloan and Newcomb, "Hytime and SMDL", in: [Selfridge-Field 1997] p.469-489.

As ever, agreement is required so that application developers may safely integrate the standard in their application. Even though SMDL unlike all the other tagging music standards is an ISO[13] standard, it seems so far to have failed the final test of acceptance by application developers.

Below is a summary list of music description standards throughout the last 200 years.

Early Number Notation (19th century and earlier)[14]:
Davantes, Kircher, Avella, Mersenne, Bontempi, Stierlein, Mine, Schulz, Rousseau, Galin-Paris-Cheve, Geisler, Teule, Gatting

19th Century Shorthand[15]:
Sauveur, la Salle, Romanos, World Music Language

Formats for Typewriter and Early Computer Age:
DARMS[16], Plain and Easy[17] and ALMA[18], WMN[19], MECOS[20], ANTOC[21], SPECO[22], NUTOC[23], Essen EsAC[24]

Computer Age: Formats for Notation Software - Binary File Formats
Encore File Format[25], Finale's Enigma[26], Syqyest, Lime's Tilia[27], Nightingale[28], Score's Score[29],

[12] The Moving Picture Experts Group (MPEG) is a working group of ISO/IEC in charge of the development of international standards for compression, decompression, processing, and coded representation of moving pictures, audio and their combination. So far MPEG has produced: MPEG-1 (approved Nov. 1992), MPEG-2 (approved Nov. 1994), MPEG-4 version 1, the standard for multimedia applications (approved Oct. 1998). and is now developing MPEG-7 the content representation standard for multimedia information search, filtering, management and processing (to be approved July 2001). It is hard to understand why it is, that until now no music representation standard has been accepted. A list of problems of developers of music representation standards, which could explain this absence of accepted standards would encompass difficulties of collaborative development efforts as well as difficulties in the intellectual effort itself. Without going into detail, the creation of music standards involves the problematic design and implementation of a) time, b) granularity, c) representation, and d) language functionality. Within the MuTaTeD projects it was decided that rather than implementing yet another language, two existing standards, SMDL and NIFF, were to be taken in order to minimise the problems outlined above.

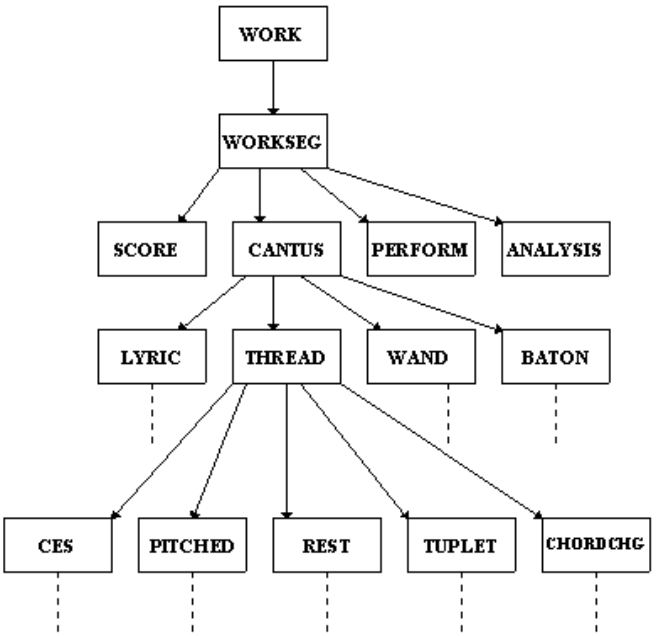
6. A Short Introduction to SMDL (Standard Music Description Language)

SMDL (Standard Music Description Language) is a HyTime application that conforms to international Standard ISO/IEC 10744.

There are four domains in SMDL:

- logical domain - contains the abstract musical content , described as "the composer's intentions with respect to pitches, rhythms, harmonies, dynamics, tempi, articulations, accents, etc.". It contains any number of `cantus' elements.
- gestural domain - contains any number of performances, each of which specifies how and where components of the logical domains are rendered in a specific performance, as in "the information added by performers".
- visual domain - contains any number of scores, each of which specifies exactly how components of the logical domain is rendered visually, as in "the information added by human editors, engravers, and typesetters".
- analytical domain - comprised of any number of theoretical analyses.



The process of creating an SMDL document instance involves generating a logical domain from a score or a performance, and (optionally) of generating a visual or gestural domain which represents all the correspondences between that score or performance and the logical domain. The relationships between the different domains are created using hyperlinks which may connect chunks of multimedia materials as well.

SMDL can be seen as the XML of music. The Standard Music Description Language (SMDL) is defined (in ISO/IEC Draft International Standard 10743) and builds upon SGML (ISO 8879) and HyTime (ISO/IEC 10744). Defined as "an architecture for the representation of music information, either alone, or in conjunction with text, graphics, or other information needed for publishing or business purposes" it was historically in its development closely related to HyTime[54] and is ex-

[54] For the history of the development of the standard SMDL, see ftp://ftp.techno.com/pub/HyTime/history/history.txt 26/02/00. and/ or http://coral.lili.uni-bielefeld.de/~hnord/hytime/ 26/02/00 and [Newcomb 1991+ 1992].

pected to be published in its revised form with compatibility with XML and HyTime2 in 2000., which was taken up by the US Defense Department. Not being interested in the music-side of things, rather only in the time-based structures, SMDL was created (loosely speaking) by extracting the music side out of HyTime. Nice thing about it is that it is a ISO standard, thus is more secure against any commercial or private pressures in order to change it. But only a few browsers handle it, and these are not available for all platforms. It is unbelievable that there has existed a very well defined standard (700 pages) for about three years, without anybody developing applications. We in Glasgow are still trying to get projects (EU and national) funded to work on platform independent applications using SMDL and NIFF in combination. We would definitely be delighted if an institution like IICM would join us in that effort.

7. A short introduction to NIFF (Notation Interchange File Format)

As Stephen Mounce writes in his introduction to NIFF:

> *"The NIFF project began in February 1994 with a meeting between technical people representing three major music notation programs and three music scanning programs. The group's goal was to define a new standard format for exchange of music notation data, which everyone agreed was long overdue in the industry.*
> *The original companies involved were: Passport Designs (publisher of Encore), San Andreas Press (Score), Coda Music Technology (Finale), Musitek (MidiScan) and TAP Music Systems/MusicWare (NoteScan). The list of advisors has continued to grow over time.*
> *In January of 1995 Coda decided to withdraw from the process (with the intention to publish their own Enigma format). Shortly thereafter, Mark of the Unicorn, Twelve Tone Systems, Opcode Systems, and TAP Music Systems/MusicWare agreed to replace Coda as financial sponsors."*[55]

Thus NIFF is the result of more than two years collaboration between major music software publishers and experts in the field of music notation/representation. NIFF files include graphical object and page layout as well as MIDI performance information.

Up to now, MIDI files have been the de facto standard for exchange of music data between programs. Although this is sufficient for playback, it is inadequate for displaying and printing of music notation. NIFF tried to answer this need with a dedicated notation score representation with its major functionality of being an interchange file format.

To sum up the positive characteristics of NIFF:

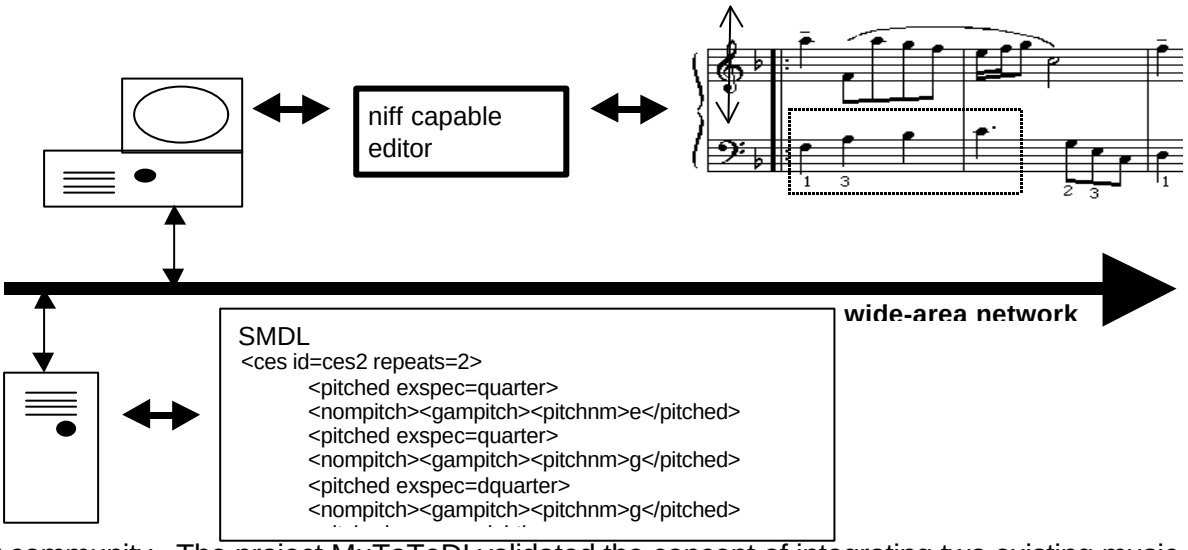
- platform-independent interchange
- intended to preserve a significant amount of visual detail
- allows representation of the most common situations occurring in conventional music
- makes provision for software developers to define their own extensions to handle the more unusual situations
- allows inclusion of Encapsulated PostScript (EPS) files and fonts to allow interchange of features not otherwise defined in the format
- the standard is open and non-proprietary.
- there are Software Developers Kits (SDKs) available

[55] Stephen Mounce (ed), "Niff Homepage", http://www.student.brad.ac.uk/srmounce/niff.html, 1/11/00

Both SMDL and NIFF seemed stable enough to start developing SMDL based and NIFF compatible services for music information retrieval. Although one may be aware of the fact that other standards are much more accepted and hyped within the music industry, and that both NIFF and SMDL are not accepted by it, they still seem to be the only standards powerful enough and close enough to being officially standardized, for developers not to be prone to the danger of working towards moving goalposts. Within this context, plans were made to set up a proof of concept project to validate the concept of integrating these two existing music representation standards.

8. MuTaTeD! – a proof of concept

Objectives of the project were: to integrate SMDL as the Model with NIFF as one possible View, and establish a standard Meta-DTD for music tagging languages, which could be used by the wide



user community. The project MuTaTeD! validated the concept of integrating two existing music representation standards. Additionally, it was to research into the development and integration of a SMDL DTD for the wider music user community and develop a web-application as a demonstrator.(see fig. 5) The work heavily influenced the "Structured Music MPEG7 proposals"[56] which were proposed in order to ensure an SMDL-compliant standard.

Fig - 5 Basic Architecture for the MuTaTeD! project

Due to the time and financial constraints of this project an early decision was taken to use freely available software development environments. For the parser and compiler the Lex/Yacc Parser Technology (lexer, parser, code generator) was chosen and a multipass compiler has been developed with this technology. To create the NIFF output files the NIFF Software Development Kit, also freely available, was used. In addition to this, we could utilize already existing multipass compilers, which convert SMDL to NIFF, developed by the CANTATE[57] project (developer: Steven Mounce). Including our multipass compilers, which also make use of the NIFF SDK we had the following compiler passes:

CANTATE	MuTaTeD!

[56] See [Boehm/Hall 1999].
[57] Cantate, Computer Access to Notation and Text in Music Libraries. http://www.svb.nl/project/cantate/cantate.htm, 11/01/00

2 Pass Compiler: NIFF --> SGML(SMDL)	Multi-Pass compiler: SMDL --> NIFF
- NIFF -> SGML(NIFF) **- SGML(NIFF) -> SGML(SMDL)**	**- SMDL --> SGML(SMDL)** **- SGML(SMDL) --> SGML(NIFF)** **- SGML(NIFF) --> C(NiffSDK) --> C-Code** **- C-Code --> NIFF binary**

The feedback from several large libraries and library projects, which have shown interest in this work, emphasized the value of having the full circle of converters from SMDL to NIFF and NIFF to SMDL available. Although the SMDL-to-NIFF converter as developed still has some restrictions in its functionality, it should be noted that MuTaTeD!, besides having prooved the concept of integrating SMDL and NIFF, it was the gfirst project to build a SMDL to NIFF converter.

8.1. The technical Set-Up

The ideal situation (see Fig. 6), as sketched below, would have been to distribute the multipass converter across server and client whilst using a platform independent client. This design would have had the advantage of client-server distribution in order to maximise the performance for the user. The conversion processes to the final binary NIFF files would be executed on the clients' machines, thus minimising the downloading time and platform dependencies. Only text-based information would be sent to the client, the binary being created within the client-side application.

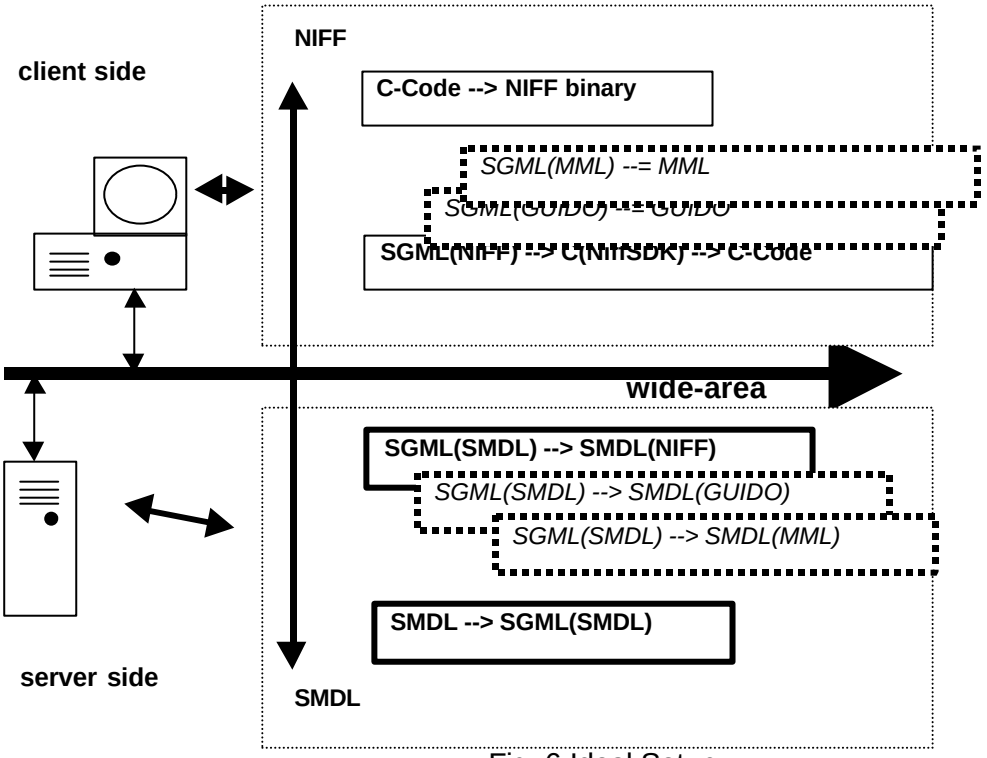


Fig. 6 Ideal Setup

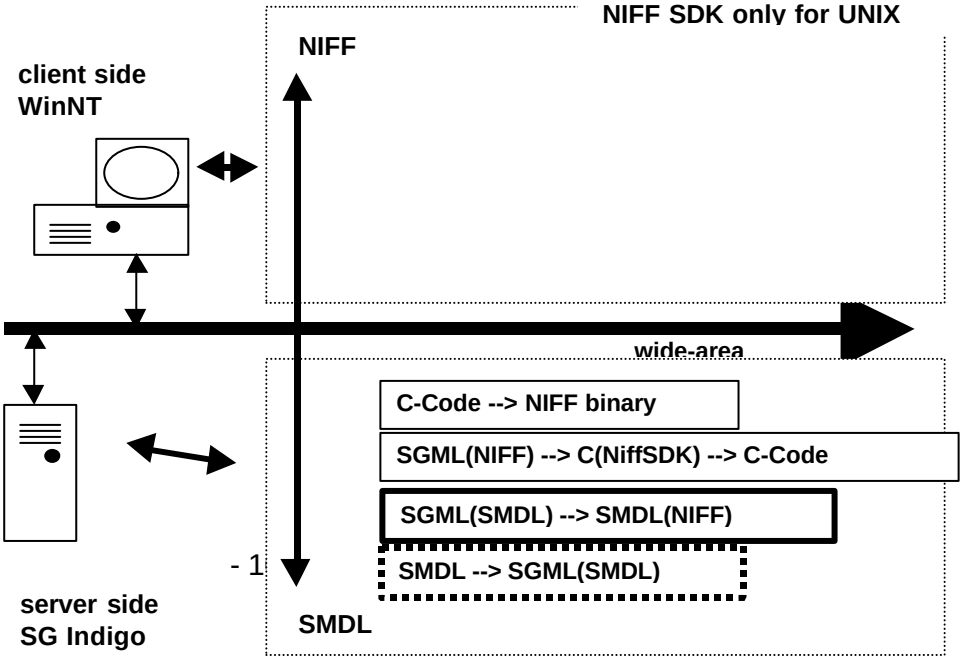
Additionally this would have the advantage of involving separate passes, allowing the modularity to add different client side converters, such



as for instance GUIDO or MML. In this way it could be easily expanded.

Facing the problem that the NIFF SDK was available only for Unix, and not having the time for tedious recompilation procedures of the software tools for WinNT, the decision was made to put all of the passes onto the server side. (see Fig. 7)

Fig. 7 Real Setup

8.2. The MuTaTeD! Multipass Compilers

A compiler contains a *lexer*, a *parser* and a *code generator*. The lexer splits up the program text into what are called 'tokens', tiny pieces of information. These are then examined by the parser, which builds a tree representing the program's structure. If the program can be parsed successfully, then the tree is well-defined and is passed on to the code generator, which walks over the tree and produces target code as it examines each node in the tree. The compiler developed in MuTaTeD! works with two passes. The first translates SMDL into an intermediate form of NIFF, called SGML(NIFF)[58]. The second translates into NIFF binary code. Each of the two passes is written using LEX and YACC. The second pass translates an SGML(NIFF) file to a C program, using the NIFF SDK. This is compiled and executed, resulting in a NIFF binary file that can then be loaded into a NIFF compatible music editor, such as LIME. (see source code excerpt Fig .8 and Fig. 9)

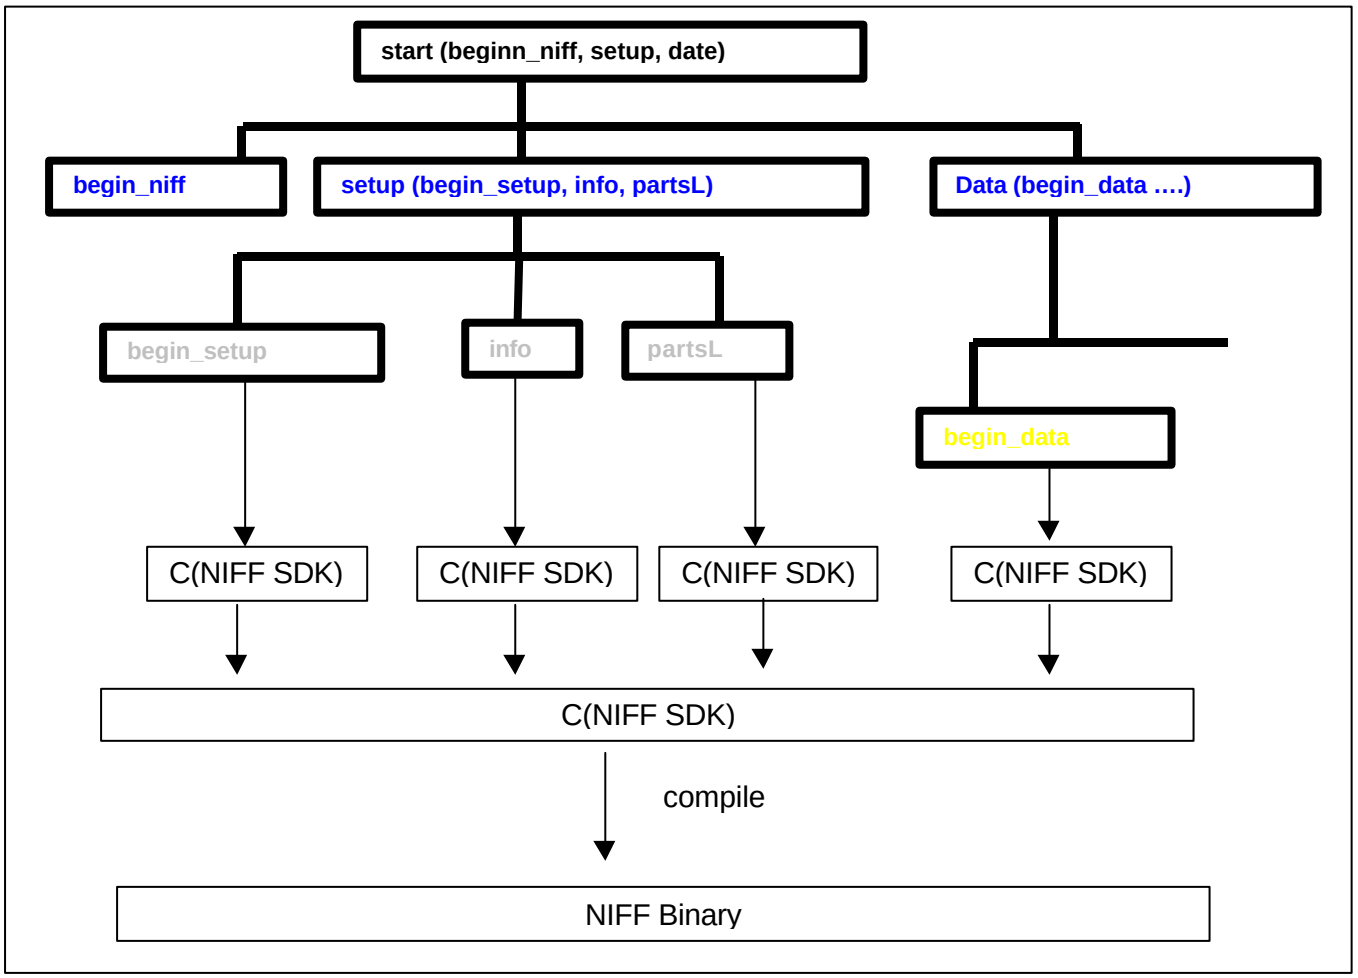


Fig. 8 Multi pass compiler, via Lex/Yacc

How the lex/yacc compilers work can shown in the following examples, deriving from the 2nd Pass, (SGML(NIFF) --> C(NIFF_SDK)):

```
start : NIFF begin_niff setup data END_NIFF end_niff

begin_niff : {printStartFile();
              printf("if (! NIFFIOStartNiff())
              doerror(\"NIFFIOStoreFormNiff failed\");\n");}
end_niff : {printf("NIFFIOEndNiff();\n");  printEndFile(); }

setup : SETUP EHJLQBVWX$LQIR$DUWV/ END_SETUP end_setup
EHJLQBVWX$ : {
printf("if (! NIFFIOStartSetupSection())
doerror(\"NIFFIOStartSetupSection failed\");\n");
          printf("if (! NIFFIOStoreDefaultCLT())
          doerror(\"NIFFIOStoreDefaultCLT failed\");\n");  }
end_setup : { printf("if (! NIFFIOchunkStringTable()) doerror
            (\"NIFFIOStringTable failed\");\n");
            printf("MyWriteStringTable();\n");
            printf("NIFFIOEndSetupSection();\n");}

LQIR : INFO begin_info VERSION INTEGER END_INFO
begin_info : {printf("if (! NIFFIOchunkNiffInfo(version, progtypeNone,
    unitsNoUnits, -1 ,-1)) doerror (\"NIFFIOStoreListSetupSection
    failed\");\n");}

$DUWV/ :  PARTSL begin_partsL part_plus END_PARTSL end_partsL
          begin_partsL : {printf("if (! NIFFIOStartParts()) doerror
    (\"NIFFIOStartParts failed\");\n");}
end_partsL : {printf("NIFFIOEndParts();\n");}

part_plus : part
part_plus part
part : PART begin_part ID IDENTIFIER NAME IDENTIFIER END_PART
begin_part : {printf("if (! NIFFIOchunkPart(0,0,0,1,-1,-1,-1)) doerror
(\"NIFFIOchunkPart failed\");\n");}

data : DATA begin_data pageL_star END_DATA end_data
begin_data : {printf("if (! NIFFIOStartDataSection()) doer-
ror(\"NIFFIOStartDataSection failed\");\n");}
end_data : {printf("NIFFIOEndDataSection();\n");}
    ….etc
    …etc
```

Fig. 8 Source Code 2nd Pass, (SGML(NIFF) --> C(NIFF_SDK))

[58] For future notation within this document, a file written in SGML and using an X DTD is described as being in SGML(X). A file written in C and using functions from the NIFF SDK is referred to as being in C(NIFF SDK).

8.3. Conclusion

Besides proving the concept of using these two standards, the use of the LEX/YACC technology enabled us to implement the converters, but also restricted our flexibility to certain extent. With LEX/YACC we had to hardcode our chosen DTD's into the converters. This is implemented differently in the follow-up project, MuTaTeD'II in which the Groveminder Technology is used. This, besides other advantages, allows for the reading in of different DTDs. NIFF, being binary, also posed some problems of accessing and searching the content. The fact that a compilation procedure has to always precede a reading in, has consequences in the design of intuitive content music retrieval out of NIFF, specifically for displaying music. So although NIFF has proved to be the powerful format, we are thinking of using another text-based representation language for future implementations.

We hope to be able to continue influencing the MPEG7 standardization process to include compatibility with SMDL. Newest developments within the finalization of the SMDL standard will include compatibility with XML and HyTime2.

Finally, MuTaTeD!'s major contribution to the music user community is the first SMDL-to-NIFF converter.

IV. Detailed project report of the implementation of the prototype

(by Dr. Cordelia Hall)

1. Summary

The goal of the project was to provide a 'proof of concept' for translation of SMDL documents into NIFF binary format. The compiler that does this has two passes. The first translates SMDL into an intermediate form of NIFF which we call SGML(NIFF). This form is a text file with SGML like tags. The second translates from this intermediate language into NIFF binary code. Each of the two passes is written using LEX and YACC.

The second pass is a little more complex than the first, because it translates an SGML(NIFF) file to a C program which uses the NIFF SDK. This is then compiled and executed, resulting in a NIFF binary file that can then be loaded into a music editor such as LIME, and browsed.

The next two sections are for interested musicians who need to use the compiler (and are willing to look at files of music in music representation languages) but do not need to modify it. The rest of this document is for programmers who need to maintain and extend the compiler.

2. How to run the compiler

The MuTaTeD! compiler is located in the directory

/usr/people/mutated/mutatedWork/Compiler

and can be run from the directory

/usr/people/mutated/mutatedWork/Compiler/Run

To run it on a file <file>.smdl formatted in SMDL, copy <file>.smdl into the directory above, then go to that directory and type

java Compiler <file>.smdl <file>.nif

The file <file>.nif will then be the binary NIFF file.

The Web demonstrator requires a script in the local cgi-bin directory of the server; this will be added by Carola later.

3. A musician's guide to the MuTaTeD! Compiler

3.1. Twinkle – an extended example

In this section, we look at several versions of Twinkle, a short, well known children's song, so that we can compare the different formats used by the two passes of the compiler.

This first format is SMDL. This initial section describes the HyTime modules needed and those needed for the SMDL DTD.

```
<?HyTime VERSION "ISO/IEC 10744:1992" HYQCNT=32>
<?HyTime MODULE base desctxt>
<?HyTime MODULE measure fcsmdu axismdu>
<?HyTime MODULE locs coordloc multloc relloc>
<?HyTime MODULE links>
<?HyTime MODULE sched splitfcs grpdex exrecon>

<!DOCTYPE work SYSTEM "smdl.dtd"
[<!ENTITY score SYSTEM "twinkle.mus">
 <!ENTITY stress SYSTEM "stress.sgm">
 <!ENTITY pitch SYSTEM "pitchgam.sgm">
 <!ENTITY ficta SYSTEM "fictagam.sgm">
 <!ENTITY length SYSTEM "notedur.sgm">
 <!ENTITY extlists SYSTEM "extlists.sgm">
]>
```

The *work* entity gives the technical description of Twinkle.

```
<work>
<axis id=virtime></axis>

&stress
&pitch
&ficta
&length
&extlists

<!-- this file was created by hand -->
```

The *cantus* represents the logical structure of the music, and it is here that the notes of Twinkle appear:

```
<cantus id=can1 bibinfo=bib1>

<tempobat id=temp1>
<proscope exspec=entire>
<projectr><profun>Moderato</profun></projectr>
</proscope></tempobat>

<extlist id=entire><extent><dimlist><dimspec>
<marklist>1<marklist>-1</extlist>
```

```
<stresuse id=su1 idr=four></stresuse>
```

This thread is Twinkle's single musical line.

```
<thread id=thread1 nominst=piano>
```

The *ces* entity represents a sequence of notes. At present, we also use it to group notes so that each *ces* gives the notes on one staff line.

The key is represented by the attribute *fictagam* . When this value is *none*, then the key is C major. If this value is *flats*<*n*> or *sharps*<*n*>, then the key has the indicated number of flats or sharps.

```
<ces id=ces1 pitchgam=pgam1 fictagam=none>
```

The entity *pitched* represents a note. The attribute *exspec* determines the length of the note. If it is *quarter*, then the note is a quarter note.

The *pitchnm* tag is followed by a letter that indicates the pitch of the note. If it is *c*, then the note is middle C. If there is an accidental, then it will appear after the note, with the following form:

```
<fictadj><nsdist>0<gsdist>n</fictadj>
```

where n is –1 if a flat, 0 if a natural, and 1 if a sharp.

Here are the notes in the SMDL representation of Twinkle:

```
<pitched exspec=quarter>
<nompitch><gampitch><pitchnm>c</pitched>
<pitched exspec=quarter>
<nompitch><gampitch><pitchnm>c</pitched>

 <nompitch><gampitch><pitchnm>g</pitched>

<pitched exspec=quarter>
<nompitch><gampitch><pitchnm>f</pitched>
<pitched exspec=quarter>
<nompitch><gampitch><pitchnm>f</pitched>
<pitched exspec=quarter>
<nompitch><gampitch><pitchnm>e</pitched>
<pitched exspec=quarter>
<nompitch><gampitch><pitchnm>e</pitched>
```

```
      <pitched exspec=quarter>
      <nompitch><gampitch><pitchnm>d</pitched>
      <pitched exspec=quarter>
      <nompitch><gampitch><pitchnm>d</pitched>
       <pitched exspec=half>
       <nompitch><gampitch><pitchnm>c</pitched>

           </ces>
```

Now that we have reached the end of the *thread* and *cantus*, here are the end tags:

```
       </thread>

</cantus>
```

SMDL also provides bibliographic information, and can provide graphic information as well:

```
<bibinfo id=bib1>
<author>Unknown</author>
<uniform>Twinkle</uniform>
<isbd>unknown</isbd></bibinfo>

<nameloc id=graphic1><nmlist>score</nmlist></nameloc>
<score id=link1 linkends="graphic1 can1" extra=A intra=A></score>
</work>
```

3.2. Twinkle – SGMLniff code produced by the first pass of the MuTaTeD! Compiler

The first section of the document is the *setup* section, which defines the part names:

```
<!DOCTYPE niff SYSTEM "intdtd.sgm" []>
<niff>
   <setup>
      <info>6b 1</info>
      <partsL><part><id>p0<name>part0</part></partsL>
   </setup>
```

The other section gives the data (the notes):

```
   <data>
```

The data is organised into pages, each of which contains one or more systems. Each system contains one or more staffs:

```
      <pageL>
           <systemL>
               <staffL>
               <stafhedC></stafhedC>
```

NIFF requires a time slice to appear after each note, giving the sum of the rests and notes read so far in the measure. At the end of each bar, another time slice gives the number of bars read so far.

```
<ts><tstype>2</tstype><top>0<bottom>4</ts>
```

The *clef* entity specifies the clef and the *octave* gives the initial octave used. If it is octave 0, then the octave contains Middle C.

```
<clef><type>treble<octave>0</octave></clef>
```

The *keysig* entity gives a number that represents the key. If that number is 0, the key is C Major. If that number is between 1 and 7, then the key signature has that number of sharps; if it is between 8 and 14, then it is one of the keys with flats (the number of flats is an offset from 7).

```
<keysig>0</keysig>
```

The time signature is given by the top and bottom values:

```
<timesig><top>4</top><bottom>4</bottom></timesig>
```

A note is represented by a *stem* and a *notehead*. A notehead has a *stafstep*, which indicates the pitch as an offset from the lowest line on the staff (which has an offset of 0). In the example here, this note is a Middle C. A notehead also has a *duration*, which is given by a fraction, and a *partid*.

If there is an accidental, then it is specified after the note in a line of the form

```
<accident>n</accident>
```

where n is 2 if a flat, 3 if a natural and 4 if a sharp is required.

```
<stem></stem>
<notehead><stafstep>-2<duration>
 <top>1<bottom>4<tag><partid>p0</partid></notehead>
<ts><tstype>2</tstype><top>1<bottom>4</ts>

<stem></stem>
<notehead><stafstep>-2<duration>
 <top>1<bottom>4<tag><partid>p0</partid></notehead>
<ts><tstype>2</tstype><top>2<bottom>4</ts>

<stem></stem>
<notehead><stafstep>2<duration>
 <top>1<bottom>4<tag><partid>p0</partid></notehead>
<ts><tstype>2</tstype><top>3<bottom>4</ts>

<stem></stem>
<notehead><stafstep>2<duration>
 <top>1<bottom>4<tag><partid>p0</partid></notehead>
<ts><tstype>2</tstype><top>4<bottom>4</ts>
<ts><tstype>1</tstype><top>4<bottom>4</ts>

3.3. Twinkle – C code produced by the second pass of the MuTaTeD! Compiler

The C files use the NIFF SDK written by Tim Butler and referred to in the first part of this report. Fortunately, the intermediate language, SGMLniff, has a structure that follows NIFF very closely. As the NIFF SDK naturally follows NIFF closely as well, the compiler is a relatively simple one in which the include section is created, then the NIFF chunk calls are inserted and finally, the C code required at the end is created.

```
#include <stdio.h>
#include <string.h>
#include "niffio.h"
```

```
#include "stdcriff.h"
extern void doerror(const char *strMessage);
void MyWriteStringTable(void);
int
main(int argc, char **argv)
{
unsigned char version[8] = "6b";
FILE          *outfp;
NIFFIOFile    *pnf;
NIFFIOStorage   *pstore;
NIFFIOChunkLengthTable *pclt;
RIFFIOSuccess success;
STROFFSET offset;
RATIONAL rat;
outfp = fopen("Test1.nif", "wb");
if (!outfp)
doerror("Can't open Test1.nif for writing");
pstore = NIFFIOStorageNewSTDC(outfp);
if (!pstore)
doerror("Can't create new NIFFIOStorage");
```

Here is where the compiler starts generating code that depends upon the tokens it reads from the SGMLniff file it parses. The **NIFFIO<name>** calls correspond roughly to SGMLniff.

```
if (! NIFFIOStartNiff()) doerror("NIFFIOStoreFormNiff failed");

if (! NIFFIOStartSetupSection()) doerror("NIFFIOStartSetupSection
failed");
if (! NIFFIOStoreDefaultCLT()) doerror("NIFFIOStoreDefaultCLT failed");

strcpy(strings[3], "vl");
for (i=0; i < 4; i++) myStbl[i].str = strings[i];
nWritten = NIFFIOStoreStbl(myStbl, 4);
if (nWritten != 4)  {doerror("Couldn't write strings");}
}
```

3.4. Twinkle – in LIME

Finally, here is the image of the binary NIFF file produced in the music editor LIME:

3.5. Limitations of the MuTaTeD Compiler

This compiler was intended to be a 'proof of concept' rather than a full-blown compiler that accepts a large variety of SMDL files. As such, it has significant limitations, and produces good results only for pieces that contain

- A single line using the treble clef
- Octaves 0, 1 and 2
- 4/4 meter
- no repeats

Pieces containing flagged notes do not translate well because there is an ambiguity that has to be resolved. A note containing a flag may be part of a beamed group or have a flag by itself, depending upon decisions to be made by the writer, and given the timespan for this project, this is best left to later work.

The second pass of the compiler is more robust and can handle chorales.

4. A programmer's guide to the implementation

This section is for the programmer who wants to extend the compiler.

There are two versions of the MuTaTeD compiler. The first is in the directory

/usr/people/mutated/mutatedWork/Compiler

and supports the Web Demonstrator. This is a stable version of the compiler that can handle enough of the SMDL language to be a 'proof of concept', but is not a real compiler. The second is under development in the directory

/usr/people/mutated/mutatedWork/Development

Both of these directories have README files that describe their contents.

4.1. Compiler directory - overview

Here is an overview of the Compiler directory and its subdirectories:

Examples_NIFF contains NIFF files produced by compilation of the test files in Examples_SMDL. These are:

Achild.nif
Alabama.nif
Chinese.nif
Larle.nif
Tchinese.nif
Twinkle.nif

Examples_SMDL contains SMDL files that can currently be compiled by the stable version of the compiler. These are:

Achild.smdl
Alabama.smdl
Chinese.smdl
Larle.smdl
Tchinese.smdl
Twinkle.smdl

SGMLniff_NIFF contains the code for the second pass of the compiler.

mk_niffCG – script that builds the object file
niffCG – object file that performs the second pass of the MuTaTeD compiler
niffCG.y – YACC file (parser)
nifflex.l – LEX file (lexical analyser)

SMDL_SGMLniff contains the code for the first pass of the compiler

mk_smdlCG – script that builds the object file
smdlCG – object file that performs the first pass of the MuTaTeD compiler
smdlyacc.y – YACC file (parser)
smdllex.l – LEX file (lexical analyser)

Run contains code that, when executed, will run the compiler (performing two passes).

CompilerScript – script that runs the compiler
Compiler.java – Java program that calls CompilerScript

The NIFF SDK is in the directory

/usr/people/mutated/mutatedWork/ O_niffsdk-1_02

It contains a subdirectory in which examples can be compiled and executed, called

niffsdk1.02/niffio/src/example/Test1

as shown in the script CompilerScript. Once the code generator of the MuTaTed! compiler has finished producing the C file containing calls to the NIFF SDK, that file is placed in the Test1 directory, and the C executable is then placed by the SDK into the directory

niffsdk1.02/niffio/test

This can then be executed with the SDK library by the command

../bin/Test1

Unfortunately, this process still produces a core file, and so that file has to be removed. The binary NIFF file is then

niffsdk1.02/niffio/test/Test1.nif

which is renamed and moved by the CompilerScript script.

5. A programmer's guide to LEX and YACC

First we discuss how a compiler works, then the software that it generally uses. Before this, we define some useful terms.

A *pointer* is a link from one piece of data to another.

A *tree* is a structure that is composed of lots of nodes, each of which has two possible shapes. The first shape belongs to the interior nodes that hold the tree together. An interior node has some data, and two pointers, each of which points to a node. The second shape belongs to a leaf node, which has data but no pointers.

A *stack* is a structure which can be viewed and accessed only from the top. A new value may be put into the stack using a *push* operation. The stack then contains that element on its top. The top element may then be removed using a *pop* operation.

A compiler contains a *lexer*, a *parser* and a *code generator*. The lexer splits up the program text into what are called 'tokens', tiny pieces of information. These are then examined by the parser, which builds a tree representing the program's structure. If the program can be parsed successfully, then the tree is well-defined and is passed on to the code generator, which walks over the tree and produces target code as it examines each node in the tree.

A *regular expression* is an expression that is composed of letters, digits and special symbols. It specifies the structure of the expression being recognised by a lexer.

5.1. A high level view of the structure of a compiler

We now go on to give a more detailed view of a compiler's structure, so that it is easier to understand what the standard software does. This is necessary if you are to alter the compiler.

A *lexer* takes a text file and converts it into a stream of pieces of data called *tokens*. These tokens each have a type. For example, given the file

"This file has 6 words in it!"

a lexer might produce the following tokens:

IDENTIFIER This
IDENTIFIER file
IDENTIFIER has
NUM 6
IDENTIFIER words
IDENTIFIER in
IDENTIFIER it
EXCLAM !

The types are passed on to the *parser*, which uses them to determine whether the file has a correct program. For example, given the file

“4 + (3 + 2 * 9)”

the lexer would produce the tokens

NUM 4
PLUS
LPAREN
NUM 3
PLUS
NUM 2
MUL
NUM 9
RPAREN

and the parser could then check its structure by failing if PLUS and MUL do not have 2 arguments and/or the parentheses do not match. If they do, then the parser could build the tree

```
          PLUS
NUM 4           PLUS
          NUM 3       MUL
                  NUM 2  NUM 9
```

A *code generator* could then traverse the tree and generate the code

4
3
2
9
*
+
+

for a stack machine, which would push all of the arguments on the stack, then pop them and apply the operators as it encountered them on the bottom of the stack. For example, it would push 4,3,2,9, then when it read *, it would know that 2 operands are required, collect them from the top of the stack, perform the multiplication and then push the result. The stack would then have 4,3,11, and the same thing would be done for each of the remaining operators + and +. Code generators usually produce a file that contains machine code such as

```
LDVAL     R1,#0002
LDVAL     R2,#0009
MUL       R3,R1,R2
LDVAL     R4,#0003
```

```
ADD     R5,R3,R4
LDVAL   R6,#0004
ADD     R7,R5,R6
```

Notice the order in which the operations take place. The code generator must traverse the tree nodes in the correct order to produce this code, and later optimise the code by reusing some of the registers R0-R7.

It used to be the case that a programmer writing a compiler would write a lexer, then the parser, then the code-generator – and do the same thing for another compiler later. This is hard work because many languages are very hard to parse, and the most successful algorithms are hard to write without careful study and lots of experience. More important, it duplicates a lot of the programming work, and makes it hard for other programmers to modify the code. Lexing and parsing are well- understood technologies now, so we have software that can do all of the work that compilers need in general, and that can accept high level programming which takes a very short time to do. The result is (usually) a compiler that has few bugs and is easily modified by other programmers who have used this software. One of the best known 'compiler generators' is YACC, which uses LEX to write the lexer and then generates a parser that produces target code as it parses.

LEX

We first describe how a LEX lexer works. A lexer has to recognise each token using a regular expression. Regular expressions are complex and you can read more about them in a book on LEX and YACC (such as *lex & yacc, by Levine, Mason, Brown, O'Reilly & Associates, 1992*). However, we describe a few simple ones here. The expression ab recognises the string "ab". If we want to recognise a string containing lots of repetitions of "ab", we write (ab)*, which accepts a string with any number of "ab"s in it, including none at all. If we use + instead of *, then the string must have at least 1 "ab" in order to be recognised.

Constructing a lexer is fairly straightforward. You first decide what token types you expect the lexer to recognise, then construct regular expressions that recognise them. The lexer will have a line for each expression, which ends with the token type you wish the lexer to return to the parser. The lexer automatically returns the token as well.

Let's consider a simple example. Suppose that we want a lexer for a small expression language that contains numbers, operators and parentheses. We need the following lines in the lexer:

```
[0..9]+     return NUM;
"+"         return PLUS;
"*"         return MUL;
"("         return LPAREN;
")"         return RPAREN;
```

YACC

We now describe how to use a YACC parser generator.

The parser generator contains a series of token types that must be specified in the first section. These are used to form a table that will be given to the lexer, so that it knows what token types are being used.

There are two tasks that are performed by the YACC parser generator. It parses the tokens returned to it, and it generates target code as it parses. We will write a little parser generator that produces the machine code given earlier. Before that, we need to provide you with a little background on parsing.

Parsers are generally written for a class of languages called the *context free* languages. A context free language is one that can be parsed by a context free grammar, a series of rules that specify the set of sentences in the language. If we think only of programming languages, then the set of sentences for a context free grammar is the set of syntactically correct programs.

Here is a grammar for the expression language we have described so far.

```
Start ::= Expression
Expression ::= PLUS Expr Expr
             | MUL Expr Expr

Expr ::= LPAREN Expression RPAREN
       | NUMBER
```

Each *rule* contains the name, followed by '::=', followed by the rule body. Rules are often called *productions*. For example, the first rule is the 'Start' rule, and the second is the 'Expression' rule. The rule body contains one or more clauses, separated by a vertical line. Each clause contains a sequence of words which may be either a token type or the name of a production.

Before looking at code generation, let's look at the parsing process. The parser attempts to match the stream of tokens against the productions. It starts with the Start production, and moves immediately to the Expression production. There, it has two possible clauses that may match. To select a clause, it looks at the token stream. If there is a PLUS token, then it accepts that token and selects the top clause; if there is a MUL token, it does the same for the bottom clause. If it succeeds in accepting all the tokens and it has finished the body of the Start production, then the expression is accepted, otherwise it is rejected by the parser.

We cheated a little by using a very simple grammar which allows the parser to select a rule by looking ahead at just one token. Many grammars require the parser to look ahead *k* tokens. Such a parser is known as an LR(k) parser, and that is close enough to what a YACC parser is for our purposes.

Now, we add code generation. The idea is very simple and easy to use: each time the parser recognises a clause, it has the opportunity to generate some code. Since LEX and YACC use C, we will write a statement in C that performs the code generation for each production in our grammar.

Before we write the C code, we have to consider what possible types of data the lexer could return. This is determined by a record structure declared at the top of the YACC code. We have decided to have a number only, which we will call 'num', so our record structure is

```
%union {
  int num;
}
```

The parser generator will need to generate register numbers (we won't worry about how many registers there are), so that will be done by the C function

```
Int registerNum = 0;
String getRegister () {return registerNum;}
Void nextRegister () {registerNum++;}
```

which appears in the last section of the YACC code.

```
Start ::= Expression

Expression ::= PLUS Expr Expr
                {
                    printf("ADD     %s,%s,%s",nextRegister(),$2,$3);
                    return getRegister();
                };
              | MUL Expr Expr
              {
                    printf("MUL     %s,%s,%s",nextRegister(),$2,$3);
                    return getRegister();
                };

Expr ::= LPAREN Expression RPAREN
                ;
        | NUMBER
                {
                    printf("LDVAL   %s,#%s",nextRegister(),$1.num);
                      return getRegister();
                };
```

Notice that two things are happening for each of the clauses that produce target code. An instruction is printed, and a register value is returned. That register value is the returned value of the clause (and therefore the rule), and is accessed using a $ sign. This is

possible because the parser generator builds an internal tree data structure as it parses, and by the time an entire clause has been recognised, all of the values required to do the code generation are present in that tree.

Let's see what happens when the parser generator looks at the following token stream:

```
MUL
NUMBER 3
LPAREN
PLUS
NUMBER 4
NUMBER 5
RPAREN
```

The first rule is the Start rule, which requires that it looks at the Expression rule. It then selects the MUL clause and parses it. This requires that the Expr production be used, and so the NUMBER clause is finished, causing the first line of target code to be emitted:

```
LDVAL       R0,#3
```

The other Expr in the MUL clause then gets parsed. There are two clauses to select from, and since LPAREN is the next token, the first is chosen. After LPAREN is accepted, the Expression production is then parsed, and the PLUS clause selected.
As the next two numbers are parsed, the code generated is

```
LDVAL       R1,#4
LDVAL       R2,#5
```

Then the PLUS clause is finished, generating the target code

```
ADD         R3,R1,R2
```

and the RPAREN token is accepted. Finally the original MUL clause is finished, generating the code

```
MUL         R4,R0,R3
```

6. The MuTaTeD! Compiler – pass 2 as an example of LEX and YACC

The second pass of the compiler for the MuTaTeD! Project has a more complex task. It must recognise an SGML language expressed by a DTD, and generate C code. The C code is composed of a sequence of calls to the NIFF SDK library, which produces the NIFF binary code. The SGML(NIFF) language is very close in structure to the NIFF language, so the code generation is straightforward.

The source language contains a sequence of tagged expressions. The parser must require that each beginning tag be matched with the end tag for most productions (some are more complex because an end tag isn't required but may appear). Then the parser must output a call to the appropriate NIFF SDK function.

6.1.The lexer for the second pass

The lexer contains a series of pairs of lines each of the form

"<tag>" return BEGIN_TAG
"\<tag>" return END_TAG

Each of these tokens represents the corresponding tag token.

6.2. The parser generator for the second pass

The parser will have productions of the form

Production ::= BEGIN_TAG p1 p2 … pn END_TAG

Roughly speaking, the associated C code will emit a call to the NIFF SDK that starts with TAG and contains arguments provided by $2..$n+1.

6.3. The lexer for the SGML(NIFF) pass

```
%{
/*
 * this is a lexer for sgml(NIFF).
 *
 */
```

The first section is for files that are included because they are useful C libraries:

```
#include <math.h>
#include "y.tab.h"

int printall = 0;
%}
```

This next section gets more space for the finite state machine that LEX generates because we are using a very simple but expensive machine by giving a long series of strings as the regular expressions

```
   /* need more space because lexer is working hard for us */

%e 10000   /* parse tree */
%p 20000   /* positions */
%n 10000   /* states */
%a 10000   /* packed transitions */

%%
```

These next lines contain the regular expressions that specify the tokens accepted by the LEX lexer.

```

```

The next regular expression matches white space

```
[\t ]+  ;
```

This matches integers

```
([0-9]+|-[0-9]+)  {yylval.num = atoi(yytext); if (printall == 1)
printf("INTEGER\n"); return INTEGER;}
```

This matches the version number

```
[0-9][a-zA-Z]  {if (printall == 1) printf("VERSION");return VERSION;}
```

This matches identifiers that start with a letter and then contains digits and/or letters

```
[a-zA-Z]([0-9]|[a-zA-Z])*   {yylval.str = yytext; if (printall == 1)
printf("IDENTIFIER\n"); return IDENTIFIER;}
```

This matches unexpected characters or a carriage return

```
.|\n    {ECHO; }
```

```
%%

yyerror(const char *msg)
{
printf("%d: %s at '%s'\n", yylineno, msg, yytext);
}
```

6.4. The parser generator for the SGML(NIFF) pass

This is the data structure that determines what values are returned along with the token type. They can either be integers (with the name ‘num’) or strings (with the name ‘str’).

```
%union {
        int num;
        char *str;
}
```

Here are the token declarations that are used to generate the table yytab.h, used by both the lexer and the parser generator.

```
/* here are the tokens */
%token <str> IDENTIFIER
%token <num> INTEGER
%token NIFF END_NIFF
       SETUP END_SETUP
       DATA END_DATA
       INFO END_INFO
       PARTSL END_PARTSL
       PART END_PART
       REPEAT END_REPEAT
       REPEATNUM END_REPEATNUM
       ID
       NAME
       PAGEL END_PAGEL
       SYSTEML END_SYSTEML
       PARTID END_PARTID
       TUPLETDS END_TUPLETDS
       TAG
       STAFFL END_STAFFL
       STAFHEDC END_STAFHEDC
       TS END_TS
       TSTYPE END_TSTYPE
       TOP END_TOP
       BOTTOM END_BOTTOM
       ACCIDENT END_ACCIDENT
       ARPEGGIO END_ARPEGGIO
       CHORDSYM END_CHORDSYM
       CLEF END_CLEF
       TYPE
       OCTAVE END_OCTAVE
       KEYSIG END_KEYSIG
       LYRIC END_LYRIC
       NOTEHEAD END_NOTEHEAD
       STAFSTEP
       DURATION
       REST END_REST
       STEM END_STEM
       TIMESIG END_TIMESIG
       TUPLET END_TUPLET
```

```
        VERSION
```

Here is the grammar for the SGML(NIFF) markup language. Recursive productions are productions that call themselves, either directly or indirectly.

```
%%

/* Grammar for SGML(NIFF) */

/*

Productions with start tags only (that appear in the example bach.niff,
since
the DTD is out of date):

id, name, tag, type, stafstep, duration

Productions that sometimes do not have end tags:

top, bottom

The others always have a start and end tag.

Recursive productions are marked prod_star or prod_plus.

APPENDIX B: SGMLniff DTD

(by Steven Mounce)

```
<!-- S.R.Mounce  Project: LIB-CANTATE/4-2016  Last Modified: 31/5/96 -->

<!-- the dtd for the intermediate sgml version of NIFF follows.
   At each stage the full specification is detailed. Recall
   that this dtd assumes the various (list)components are in
   the correct order. Also, it (for the moment) ignores MIDI
   information. Note that it may be worth incorporating the
   RIFF INFO list which contains  comments about the piece
   see p27
   note on tags: any tag can be placed (theoretically) on any
   chunk. It is up to the reading program to interprete (or
   ignore) it. My program will handle only the most basic tags
   (i.e. logical info).
   To check: are the following definitely only graphical?
   staff groupings list (and hence chunks)
   line chunk
   -->

<!ELEMENT niff  - o (setup, data)>
<!-- +tags?-->
<!-- RIFFINFOL is assumed not to be needed (handled/ignored) by
 previous program component.chunkLengthTCH is utilized by the NIFF
 parser, ignored by the IFG.stringTabCH is used and discarded by IFG.
 defValCH,fontDesL,custGraphL are all concerned with fonts and
 graphics. -->

<!ELEMENT setup - o (info, partsL) ><!-- staffgrpL would follow parts
                                      if it is in struc -->

<!ELEMENT info - o (#PCDATA) >

<!-- info content is the version followed by an integer from the
following
      set (neg 1,1,2,3,4,5,6)
 The number denotes the source of the file as follows:
 neg 1 no value/other
 1 engraving program
 2 scanning program
 3 MIDI interpreter
 4 sequencer
 5 research program
 6 educational program
 -->

<!ELEMENT partsL - o (part)+ >

<!ELEMENT part - o (id, name) >
